OS module

All standard Lua os module functions are supported and some additional functions are added:

copy(from_file, to_file)

res = os.copy(from_file, to_file)

Copy file "from file" to "to file". If the destination file exists, it will be overwritten.

Params:

from file: string, file name

to_file: string, name of the new file

Returns:

res: 0 on success, error code otherwise

mkdir(name)

res = os.mkdir(name)

Create new directory.

Params:

name: string, new directory name

Returns:

res: 0 on success, error code otherwise

rmdir(name)

res = os.rmdir(name)

Remove existing directory.

Params:

name: string, directory name

Returns:

res: 0 on success, error code otherwise

exists(name)

res = os.exists(name)

Check if the file or directory exists.

Params:

name: string, file or directory name

Returns:

res: 1 if file exists, 2 if directory exists, negative error code otherwise

list(filespec)

os.list(filespec)

List content of the file system directory to stdio

optional; string, file specification, can contain dir names and wildchars filespec:

("MRE*.vxp")

Returns:

None

compile(name)

os.compile(name)

Compile lua source file to bytecode file. Creates ".lc" file with the same base name as lua source file

Params:

string, lua source file name, must have ".lua" extension name:

Returns: none

shell_linetype(type)

Ltyp = os.shell_linetype(type)

Set or get Lua interactive shell input line type. By default, the **simple** input type is used where the user can only input characters, use Backspace key to delete last char and accept the line with Enter.

Advanced input type can be selected where some line editing functions are enabled. Left/Right arrow, Home and End keys can be used to navigate through line, Backspace and Del to delete. Previously entered lines can be accessed using Up/Down arrow keys.

To use the advanced type, used terminal emulator must have ANSI/VT100 emulation.

Params:

0: simple type; 1: advanced type; if none is given, returns current type type:

Returns:

current input line type ltyp:

table2str(tbl [,list])

tstr = os.table2str(tbl)

os.table2str(tbl,1)

Returns string representation of Lua table or lists the table content on terminal.

Params:

tbl: Lua table

list: optional; if 1, list table content on terminal

Returns:

tstr: string representation of the table (if *list*=0 or not given)

SYS module

Functions specific to RePhone/Xadow GSM+BLE.

sys.ver()

lv, fh, bd = sys.ver()

Returns version information.

Params: none Returns:

lv string, lua version

fh string, firmware host version bd string, firmware build date

mem()

lua_used, lua_total, c_heap = sys.mem()

Returns memory information.

Params: none Returns:

lua_used currently used memory for Lua stack in bytes lua_total total memory available for Lua stack in bytes c_heap total heap size available for C functions in bytes

battery()

bat = sys.battery()

Returns battery level in %. ADC module can be used to get more precise battery voltage.

Params: none Returns:

bat battery level in % of full charge

ledblink([led_id])

led = sys.ledblink([led_id])

Set or get current system LED blink. System LED blinks once per second. Any of the RGB leds can be selected.

led id optional; LED gpio pin,

predefined constants REDLED, BLUELED, GREENLED can be used

Value 0 can be used to disable LED blink Without parameter returns current led used.

Returns:

led currently used LED

usb()

res = sys.usb()

Returns the USB cable status, connected or not.

Params: none Returns:

res USB cable status: 0 not connected; 1 connected

wdg([wdg_tmo])

res = sys.wdg([wdg_tmo])

Set or get watchdog timeout.

Watchdog timer can be set to the values 10 ~ 3600 seconds. The value is saved in system parameters and *sys.saveparams()* function must be executed for new value to be remembered. The new value will take effect after next reboot.

If called without parameters, the current wdg timeout is returned.

Params:

wdg_tmo optional; watchdog timeout in seconds

Returns:

res current or new watchdog timeout in seconds

c_heapsize([size])

res = sys.c_heapsize([size])

Set or get C heap size.

The heap size used for C functions can be set to the values 32K ~ 256K in 32K increments. The value is saved in system parameters and *sys.saveparams()* function must be executed for new value to be remembered. The new value will take effect after next reboot.

If called without parameters, the current C heap size is returned.

Params:

Size: optional; C heap zize in bytes; will be rounded to 32K

Returns:

res current or new C heap size in bytes

noacttime([noact_tmo])

res = sys.noacttime([noact_tmo])

Set, reset or get no activity timeout.

If no activity is detected in Lua shell (no user input), the system is shutdown after no activity

timer expires.

If called without parameters, the current no activity timeout is returned.

Params:

noact_tmo optional; > 0 set no activity timeout in seconds

0 reset no activity timeout

no parameter: return current value

Returns:

res current or new no activity timeout in seconds

shutdown()

sys.shutdown()

Shutdown system.

If wakeup interval is defined, system wakeup will be automatically scheduled to next interaval.

Warning: if USB is connected, the system will automatically reboot after shutdown!

Params:

none

Returns:

none

reboot()

sys.reboot()

Reboot system.

In Lua shell Ctrl+D can be also used to reboot.

Short pres on power button can be also used to reboot.

Params:

none

Returns:

none

wkupint([wkup_int])

res = sys.wkupint([wkup_int])

Set or get wakeup interval.

Wake up interval can be set to enable automatic wakeup in regular intervals.

Params:

wkup_int optional; wakeup interval in minutes (values > 0 are accepted)

no parameter: return current value

Returns:

res current or new wakeup interval in minutes

schedule(val)

sys.schedule(val)

Schedule next wake up or alarm.

val wakeup or alarm time

0: wakeup or alarm on next wakeup interval > 0 wakeup or alarm after 'val' seconds

table wakeup or alarm on specific time, table format:

{year=yyyy, month=mm, day=dd, hour=hh, min=mn, sec=ss}

Returns:

none (logs info if enabled)

onshutdown(cb_func)

sys.onshutdown(cb_func)

Set callback function to be executed before shutdown. If called without parameter, disables the callback.

Params:

cb_func lua function to be executed on shutdown, prototype

function cb func(res)

res integer, shutdown reason

Returns:

onreboot(cb_func)

sys.onreboot(cb_func)

Set callback function to be executed before reboot.

If called without parameter, disables the callback.

Params:

cb_func lua function to be executed on reboot, prototype

function cb func(res)

res integer, reboot reason

Returns:

none

onalarm(cb_func)

sys.onalarm(cb_func)

Set callback function to be executed on RTC alarm. If called without parameter, disables the callback.

Params:

cb_func lua function to be executed on RTC alarm, prototype

function cb_func(res)

res integer, always 0

Returns:

none

onkey(cb_func)

sys.onkey(cb_func)

Set callback function to be executed on powr ker UP or DOWN. If called without parameter, disables the callback.

Warning: LONG press (> 2 sec) will shutdown/reboot the system!

Params:

cb_func lua function to be executed on power key up/down, prototype

function cb_func(res)

res integer; 1: key UP, 2: key down

Returns:

none

retarget(stdio_id)

res = sys.retarget(stdio_id)

Change stdio (input/output device). All input and output will be redirected to the new device.

Params:

stdio_id id of the new device

0 redirect to **usb serial port** (/dev/ttyACM0 on Linux)

1 redirect to hw UART port

2 redirect to **bluetooth SPP** (must be configured)

Returns:

res: true on success, false on error

tick()

tick = sys.tick()

Returns time elapsed from system (RTC) start in micro seconds.

Params:

none

Returns:

res time from system start in micro seconds

elapsed(from_time)

interval = sys.elapsed(from_time)

Returns time elapsed from earlier time (usually from sys.tick() function) in micro seconds.

Params:

from time: earlier time in micro seconds

Returns:

res: elapsed time in micro seconds

random([maxval] [,minval])

rnd= sys.random(from_time)

Returns random number. Optional limits can be set.

minval optional; mamal random number to return optional; maximal random number to return

Returns:

rnd random number

get_params()

par = sys.get_params()

Get current system parameters in string representation.

System parameters is special Lua table __**SYSPAR** which can contain the parameters used on system boot. The table can be saved to the special user flash area (not visible externally) and is read on boot.

Params:

nil Returns:

par string representation of __SYSPAR table read from system flash area

negative number on error

get_sysvars()

c_heap, wdg = sys.get_sysvars()

Get current system variables in string representation.

System variables are special Lua variables which are set on system boot. Thay are saved to user flash area (not visible externally) and are read and set on boot.

For now only C heap size and watchdog timeout value are used

Params:

nil Returns:

c heap C heap size read from system flash

wdg wdg timeout value read from system flash

save_params()

sys.save_params()

Save system parameters and system variables to user flash.

System parameters is special Lua table __**SYSPAR** which can contain the parameters used on system boot. The table can be saved to the special user flash area (not visible externally) and is read on boot.

System variables are special Lua variables which are set on system boot. Thay are saved to user flash area (not visible externally) and are read and set on boot.

For now only C heap size and watchdog timeout value are used

Params:
 nil

Returns:
 par string representation of __SYSPAR table read from system flash area negative number on error

gpio module

CDTO	Function in gpio module	Voltage (V)	Connector

^(*) ADC, Battery voltage

mode(pin, mode)

gpio.mode(pin, mode)

Set the operating mode for selected GPIO pin.

Params:

pin: GPIO pin number, see GPIO table for available pins

mode: pin mode, use global constants:

INPUT, OUTPUT, INPUT_PULLUP, INPUT_PULLDOWN

Returns:

none, error if not valid pin or mode

write(pin, level)

gpio.write(pin, level)

Set the pin output to HIGH (1) or LOW (0). Pin mode must be set to output.

Params:

pin: GPIO pin number, see GPIO table for available pins level: pin level, use global constants: HIGH or LOW

Returns:

none, error if not valid pin or mode

toggle(pin)

gpio.toggle(pin)

Toggle the pin output HIGH -> LOW or LOW -> HIGH. Pin mode must be set to output.

Params:

pin: GPIO pin number, see GPIO table for available pins

Returns:

none, error if not valid pin or mode

read(pin)

state = gpio.read(pin)

Set the pin output to HIGH (1) or LOW (0). Pin mode must be set to output.

Params:

pin: GPIO pin number, see GPIO table for available pins

Returns:

state: pin state: 0 or 1

error if not valid pin or mode

pwm_start(pin)

gpio.pwm_start(pin)

Configure selected GPIO pin for PWM operation.

Params:

pin: GPIO pin number, see GPIO table for available pins

Returns:

none, error if PWM mode not available on pin

pwm_stop(pin)

gpio.pwm_stop(pin)

Stop PWM on selected pin.

Params:

pin: GPIO pin number, see GPIO table for available pins

Returns:

none, error if pin not opened for PWM

pwm_clock(pin, clksrc, div)

gpio.pwm_clock(pin, clksrc, div)

Set the main PWM clock source.

Main PWM clock (pwm_clk) is set to 13000000 / <u>div</u> or 32768 / <u>div</u> !!

Params:

pin: GPIO pin number, see GPIO table for available pins clksrc: PWM clock source: 0 -> 13MHz; 1 -> 32.768 kHz

div: division 0->1, 1->2, 2->4, 3->8

Returns:

none, error if pin not opened for PWM

pwm_count(pin, count, tresh)

gpio.pwm_count(pin, count, tresh)

Set PWM in count mode.

PWM FREQUENCY is: pwm_clk / count

Params:

pin: GPIO pin number, see GPIO table for available pins

count: the pwm cycle: 0 ~ 8191

tresh: treshold: value at which pwm gpio goes to LOW state: 0 ~ count

Returns:

none, error if pin not opened for PWM

pwm_freq(pin, freq, duty)

gpio.pwm_freq(pin, freq, duty)

Set PWM in frequency mode. PWM FREQUENCY is: freq

pin: GPIO pin number, see GPIO table for available pins

freq: the pwm frequency in Hz: 0 ~ pwm clk

duty: PWM duty cycle: 0 ~ 100

Returns:

none, error if pin not opened for PWM

eint_open(pin, [tpar])

res = gpio.eint_open(pin, [tpar])

Configure selected GPIO pin for external interrupt (EINT) operation.

Not all parameters have to be present in tpar, is some parameter is missing, default value is used.

Note: use gpio.mode() to configure the pin as input and if pullup/pulldown is used.

Params:

pin: GPIO pin number, see GPIO table for available pins

tpar: optional; Lua table with eint parametersmode(pin, mode)

autounmask: 1: unmask after callback; default 0

autopol: 1: auto change polarity after callback; default 0
 sensitivity: 0: level sesitive; 1: edge sensitive; default 1
 polarity: 0: high->low trigger; 1: low->high trigger; default 0
 deboun: 1: enable HW debounce, 0: disable it; default 1

debountime: HW debounce time in msec: default 10

count: if >0, callback function will be executed after 'count' interrupts

Returns:

res: 0 if OK, negative number on error

eint_close(pin)

res = gpio.eint_close(pin)

Close selected GPIO pin as external interrupt (EINT) pin.

Params:

pin: GPIO pin number, see GPIO table for available pins

Returns:

res: 0 if OK, negative number on error

eint_mask(pin, mask)

res = gpio.eint_mask(pin, mask)

Mask selected GPIO pin EINT.

If autounmask option is not set, next interrupt must be enabled in callback function.

pin: GPIO pin number, see GPIO table for available pins

mask: 0: mask (disable) EINT operation; 1: unmask (enable) EINT operation

Returns:

res: mask value if OK, negative number on error

eint_on(cb_func)

gpio.eint_on(cb_func)

Set Lua callback function to be executed on external interrupt (EINT). If called without parameter, disables the callback.

Params:

cb func lua function to be executed on EINT, prototype

function cb_func(pin, value, count, time)

pin integer, pin number on which interrupt occurred

value pin level

count total number of interrupts

time

Returns:

none

adc_config(chan, [period, count])

res = gpio.adc_config(chan, [period, count])

Configure selected ADC channel pin for ADC operation.

ADC channel must be configured before start function can be used.

Available channels are:

0: Battery voltage

1: ADC value on GPIO-1 (ADC15)

2: ADC value on GPIO-2 (ADC13)

ADC value on GPIO-3

Params:

chan: adc channel

period: optional; measurement period in msec; default 5 msec

Count: optional; how many measurement to take before issuing the result,

time between measurements is 'period'; default 1

time between results is 'period' * 'count'

Returns:

res: 0 if OK, negative number if error

adc_start(chan, [repeat], [cb_func])

res = gpio.adc_start(chan, [repeat], [cb_func])

Start ADC measurement on selected channel and return result if no callback function is given..

chan: adc channel configured with gpio.adc_configure repeat: optional; repeat the measurement 'repeat' times;

1: measure only once

>1000: continuous measurement

default 1; only valid when callback function is given

cb_func: optional; Lua callback function to be executed on adc result

function cb_func(ival, fval, chan)
ival integer ADC value
fval float ADC result

chan channel on which the measurement is taken

Returns:

res: negative number if error

float ADC result if no callback function is given in V

0 if callback function given and no error

adc_stop(chan)

res = gpio.adc_stop(chan)

Stop ADC measurement on selected channel if the channel was configured for continuous/repeat measurement.

Params:

chan: adc channel configured with gpio.adc_configure

Returns:

res: 0 if ok, negative number if error

2 channel was not configured for repeat measurement

i2c module

I2c supports hardware i2c on GPIO43&GPIO44.

3.3V interface is available on 0.1" pins and 11pin connector with pullup resistors (10K) included. On 35pin connector, the pins are 2.8V and pullup resistors must be externally provided.

setup(addr [,speed])

speed = i2c.setup(addr [,speed])

Configures i2c interface. Slave address is 7-bit.

Fast mode or high speed mode is automatically selected based on 'speed' argument. For speed <= 400 fast mode is selected, for speed > 400 high speed mode is selected. Maximum speed is 6500 kHz, minimum 12 kHz.

Params:

addr: slave device 7-bit address

speed: optional; transfer speed i kHz, 12~6500; default 100

Returns:

speed: actual transfer speed, negative number on error

write(data1 [,data2] [,dataN])

res = i2c.write(data1 [,data1] [,dataN])

Send data to i2c slave.

Data can be given as 8-bit number, table of 8-bit numbers or string. Up to 10K bytes can be sent at once.

Params:

data: data to be sent to i2c device; number, lua table or lua string

Returns:

res: number of bytes sent to device, negative number on error

read(size [,format])

res = i2c.read(size [,format])

Receive data from i2c slave.

Data can be received to lua string, string of hex values or lua table. Up to 10K bytes can be received at once.

size: number of bytes to receive, 1 ~ 10240

format: optional; if not given, data are received to lua string

"*h" receive to string of hex values separated by ";"

"*t" receive to lua table

Returns:

res: lua string or lua table containing received data

nil on error

txrx(data1 [,data2] [,dataN], size [,format])

res = i2c.txrx(data1 [,data1] [,dataN], size [,format])

Send data to i2c slave and receive data.

Data can be given as 8-bit number, table of 8-bit numbers or string. Maximum of 8 bytes can be sent, up to 10240 bytes can be received.

Params:

data: data to be sent to i2c device; number, lua table or lua string, max 8 bytes

size: number of bytes to receive, 1 ~ 10240

format: optional; if not given, data are received to lua string

"*h"receive to string of hex values separated by ";"

"*t" receive to lua table

Returns:

res: lua string or lua table containing received data

nil on error

close()

res = i2c.close()

Close i2c interface.

Params:

nil

Returns:

res: status; 0 if OK, negative number on error

Spi module

spi module supports hardware spi on GPIO27-29.

SPI pins are available only on 35pin connector (or expansion board) as 2.8V interface.

Use **level shifters** if connecting to higher voltage device!

CS output pin can be defined in setup, if defined it is automatically activated (set LOW) during the transfer.

Additional output pin (DC) can also be defined. If defined, it is used in some functions.

setup([config])

res = spi.setup([config])

Configures SPI interface.

Configuration options are given in form of lua table.

Params:

config: lua table containing configuration options in form option=value

mode spi transfer mode, 0 ~ 3; default 0 endian endianess; 0: little; 1: big; default 0

msb bit transfer mode; 0: send LSB first; 1: send MSB first; default 1

speed SPI transfer speed in kHz; 125 ~ 16000; default 6400 cs CS (chip sellect) output gpio pin; default: not used

dc DC output gpio pin; default: not used

Returns:

res: result: 0 if OK, negative number on error

write(data1 [,data2] [,dataN])

res = spi.write(data1 [,data1] [,dataN])

Send data to SPI device.

Data can be given as 8-bit number, table of 8-bit numbers or string.

Maximum 16384 bytes can be sent.

Params:

data: data to be sent to spi device; number $(0\sim255)$, lua table or lua string

Special strings can be used for control:

"*c" send first byte as command, DC (if defined) will be set LOW before first byte

transfer and reset to HIGH after the first byte is transferred

"*s" CS will not be deactivated (set to HIGH) after transfer

Returns:

res: number of bytes sent to device, negative number on error

read(size [,control])

res, data = spi.read(size [control])

Receive data from SPI slave.

Data can be received to lua string, string of hex values or lua table. Maximum 16384 bytes can be received.

Params:

size: number of bytes to receive, 1 ~ 16384

control: optional; more than one control strings can be given

if none of "*h", "*t" is present, data are received to lua string

"*h"receive to string of hex values separated by ";"

"*t" receive to lua table

"*s" CS will not be deactivated (set to HIGH) after transfer

Returns:

res: number of bytes read from device, negative number on error

Data: lua string or lua table containing received data

txrx(data1 [,data2] [,dataN] [,control], size)

bsent, brecv, data = spi.txrx(data1 [,data2] [,dataN] [,control], size)

Send data to SPI slave and receive data in same transaction. Data can be given as 8-bit number, table of 8-bit numbers or string. Maximum of 16384 bytes can be sent and received.

Params:

data: data to be sent to SPI device; number (0~255), lua table or lua string

size: number of bytes to receive after sending

control: optional; more than one control strings can be given

if none of "*h", "*t" is present, data are received to lua string

"*h" receive to string of hex values separated by ";"

"*t" receive to lua table

'*s" CS will not be deactivated (set to HIGH) after transfer

"*c" send first byte as command,

DC (if defined) will be set LOW before first byte transfer and reset to HIGH after the first byte is transferred

"w" include in read data the data received during sending.

brecv will be size+bsent

Returns:

bsent: number of sent bytes, negative number on error

brecv: number of received bytes

data: lua string or lua table containing received data

close()

res = spi.close()

Close SPI interface.

Params:

nil

Returns:

res: status; 0 if OK, negative number on error

net module

To get the status of the UDP or TCP connection execute print(ref).

To enable garbage collector to free the data used by the connection, execute **ref=nil**. ref is the reference to tcp or udp connection obtained by tcp_create or udp_create function. GPRS must be configured with setapn() function before using any of net functions.

tcp_create(host, port, cb_func, [data])

Tcp_ref = net.tcp_create(host, port, cb_func, [data])

Creates TCP connection and connects to 'host' on 'port'.

'host' can be IP address or domain name.

If string 'data' is given, it will be sent to host after connection.

Params:

host: host IP or domain name

port: integer, tcp port to connect to (1 ~ 65535)

cb_func: Lua callback function, prototype:

function cb_func(tcp_ref, event) tcp_ref tcp connection

event tcp event which caused the call:

1: tcp is connected, can send data

2: more date can be sent3: data ready for read

4: pipe broken, disconnected5: host not found, not connected

6: connection closed

data: optional; string data to send after connection

Returns:

tcp_ref: reference to tcp connection to be used in other function

tcp_connect(tcp_ref, host, port, [data])

res = net.tcp_connect(tcp_ref, host, port, [data])

Connects to already created tcp connection. If tcp connection is connected, it is disconnected first. 'host' can be IP address or domain name.

If string 'data' is given, it will be sent to host after connection.

Params:

tcp_ref: tcp reference obtained with *net.tcp_create()*

host: host IP or domain name

port: integer, tcp port to connect to (1 ~ 65535) data: optional; string data to send after connection

Returns:

res: 0 if OK, negative number if error

tcp_write(tcp_ref, data)

res = net.tcp_write(tcp_ref, data)

Send data to tcp connection. Tcp connection must in connected state.

tcp_ref: tcp reference obtained with net.tcp_create()

data: string data to send

Returns:

res: 0 if OK, negative number if error

tcp_read(tcp_ref, size)

res, data = net.tcp_read(tcp_ref, size)

Read data from tcp connection.

This function can be used from callback function on read event.

Params:

tcp ref: tcp reference obtained with net.tcp create()

size: maximum size of data to read

Returns:

res: size or read data, negative number if error

data: string, read data; nil if error

udp_create(port, cb_func)

udp ref = net.udp create(port, cb func)

Creates UDP connection on local port 'port'. No connection is made.

Params:

port: integer, local port (1 ~ 65535) cb_func: Lua callback function, prototype:

> function cb_func(udp_ref, event) udp_ref udp connection

> > event udp event which caused the call:

2: more date can be sent3: data ready for read4: pipe broken, disconnected

6: connection closed

data: optional; string data to send after connection

Returns:

udp_ref: reference to udp connection to be used in other function

udp_write(udp_ref, host, port, data)

res = net.udp_write(tcp_ref, host, port, data)

Connect to 'host' on UDP port 'port' and send data using udp connection 'udp_ref'. Response will be handled by callback function.

udp ref: udp reference obtained with net.udp create()

host: host IP or domain name

port: integer, udp port to connect to (1 ~ 65535)

data: string data to send

Returns:

res: 0 if OK, negative number if error

udp_read(udp_ref, size)

res, data = net.udp_read(udp_ref, size)

Read data from udp connection. This function can be used from callback function on read event.

Params:

udp_ref: udp reference obtained with net.udp_create()

size: maximum size of data to read

Returns:

res: size or read data, negative number if error

data: string, read data; nil if error

close(ref)

res = net.close(ref)

Close TCP or UDP connection. TCP connection will be disconnected if connected. To enable garbage collector to free the data used by the connection, execute **ref=nil**, where ref if the reference to tcp or udp connection obtained by tcp create or udp create function.

Params:

ref: udp | tcp reference obtained with net.tcp_create() or net.udp_create()

Returns:

res: 0 if OK, negative number if error

ntptime(tz, [cb_func])

net.ntptime(tz, [cb_func])

Update RTC date-time from ntp server.

The function runs in background until it gets the time from ntp server or timeout (30 sec) expires. If callback function is given, it is executed after the time is set or error. If no callback function is given, debug info is printed.

tz: time zone, -12 <= tz <= 14

cb func: optional; Lua callback function, prototype:

function cb func(res)

res integer, 0 if time updated, -1 on error

Returns: None

setapn(ref)

res = net.setapn(apn_par)

Configure GPRS APN.

GPRS connection parameters can be obtained from mobile provider.

Params:

apn_par: Lua table with APN parameters:

apn: GPRS provider APN

useproxy: optional; proxy needed for connection;

1 use proxy; 0 do not useproxy; default 0

Used only if *useproxy=1*:

proxy: proxy IP or domain name proxyport: proxy port (1 ~ 65535)

proxytype: optional; the type of the proxy connection; default 0

0: The 'not specified' type

The WSP, Connection less type
 The WSP, Connection oriented type

3: The WSP, Connection less, security mode type
4: The WSP, Connection oriented, security mode type
5: The WTA. Connection less, security mode type

6: The WTA type, Connection oriented, security mode type

7: The HTTP type

8: The HTTP - enable TLS type

9: The STARTTLS type

proxyuser: optional; proxy user name; default ""
proxypass: optional; proxy password; default ""

Returns:

res: 0 if OK, negative number if error

https module

This module supports the tcp communication using http protocol.

It can be used to communicate with http server with or without SSL.

Use URL which starts with http://.... to connect without SSL.

GPRS must be configured with setapn() function before using any of https functions.

get(url [,fname | buf_size])

res = https.get(url [,fname | buf_size)

Connect to http(s) server and get the response.

The response is handled by **Lua callback function** which has to be set using *https.on()* function before using this function.

The response can be received to buffer or to the file.

If receiving to buffer, maximum buffer length can be specified to limit the amount of data received.

If the second (optional) parameter is given and it is of the **string** type, response will be saved to file. If the second (optional) parameter is given and it is of the **integer** type, response will be saved to buffer of that maximum size.

See https.on() function for details on response handling;

Params:

url: string; server url, can contain parameters

fname: optional; if given, the response will be saved to file with the name 'fname'

buf_size: optional; max buffer size: 1K ~ 128K; default: 16K

Returns:

res: 0 if OK, negative number on error

post(url)

res = https.post(url, post_data)

Connect to http(s) server, post data and get the response.

The response is handled by **Lua callback function** which has to be set using *https.on()* function before using this function.

The response can be received to buffer or to the file.

If receiving to buffer, maximum buffer length can be specified to limit the amount of data received.

If the second (optional) parameter is given and it is of the **string** type, response will be saved to file. If the second (optional) parameter is given and it is of the **integer** type, response will be saved to buffer of that maximum size.

If *post_data* is **string**, the data is posted as **Content-Type: application/**x-www-form-urlencoded This way you can post json string.

If *post_data* is Lua **table**, the data is posted as *multipart* data. The table must contain parameters in the form *param name = value*, where *value* can be string or number.

If *param_name* is "**file**", then the file with name given in *value* is posted.

Only **one** file can be included in post data.

See https.on() function for details on response handling.

url: string; server url, can contain parameters post data: string or Lua table containing post data

fname: optional; if given, the response will be saved to file with the name 'fname'

buf_size: optional; max buffer size: 1K ~ 128K; default: 16K

Returns:

res: 0 if OK, negative number on error

on(method [,cb_func])

res = https.on(method [, cb_func])

Register Lua callback function which will be executed on received data event. If no cb_func is given, existing (if any) callback function is unregistered.

Params:

method: string; event on which the function will be executed:

"header" execute function when response header is received "response" execute function when response data are received

cb_func: optional; Lua callback function

header prototype:

function cb_func(hdr)

hdr string; received response header

response prototype:

function cb func(state, data, len, more)

state receive status:

1: data received to buffer

3: data received to buffer and contains non printable characters probably binary data

2: data received to file

-1: receiving to string failed

-2: receiving to file failed

data string; received response data

"__Receive_to_File__" if receiving to file

len length of the received data

more if receiving to buffer, length of the data which could not be saved

to buffer

If receiving to file, negative number on error

Returns:

Res: status:

-1: error, noting changed0: callback unregistered1: callback registered

cancel()

https.cancel()

Cancel http(s) unfinished function.

Can be used if previous **get** or **post** function resulted in unclosed connection.

```
Params:
nil
Returns:
```

nil

getstate()

state = https.getstate()

Get the curreth http(s) state.

New **get** or **post** function can be executed only if the state is **0**.

```
Params:
    nil

Returns:
    state: https state:
    0: idle, ready for new request
    1: receiving to buffer
    2: receiving to file
```

Callback function example

Here is an example of using "response" callback function to process response from server:

```
function onresp(state, data, len, more)
    if (state == 1) or (state == 3) then
        print("Received to buffer")
        if more > 0 then
            print(("Partial data received: %d of %d"):format(len, len+more))
            print("Data received, length: "..len)
        end
        if (len < 3000) and (state == 1) then
            print(data)
       elseif state == 3 then
           print ("Data contains non printable characters")
        end
    elseif state == 2 then
        print("Received to file")
        if more < 0 then
            print("Error receiving to file, received len: "..len)
            print("File saved successfuly, len: "..len)
        end
    else
        print(("Error: state=%d, len=%d, more=%d"):format(state, len, more))
    end
end
https.on("response", onresp)
```

email module

This module supports sending email.

If port parameter is 25, the function uses regular smtp protocol, otherwise SSL connection is used.

GPRS must be configured with *setapn()* function before using any of email functions.

send(param)

res = email.send(param)

Connect to SNTP server and send email to recipient.

```
param: Lua table containing email parameters
             "host"
                              SMTP server domain or IP address
             "port"
                              SMTP server connection port
             "user"
                              optional; user name
             "pass"
                              optional; user password
             "to"
                          recipient's email address
             "from"
                              sender's email
             "from name"
                              optional; sender's name; default: same as "from"
             "subject"
                              optional if msg is given; email subject
             "msg"
                              optional if subject is given; email message body
Returns:
    res:
             0 if OK, negative number on error
Example:
eml = {
    host="smtp.gmail.com",
    port=465,
    user="mygmail@gmail.com",
    pass="my_gmail_password"
    to="recipient@gmail.com",
    from="mygmail@gmail.com",
from_name="rephone",
    subject="Test",
msg="test email message from RePhone" }
res = email.send(eml)
```

ftp module

This module supports FTP communication. Uses PASV mode for communication. GPRS must be configured with *setapn()* function before using any of ftp functions.

connect(param)

res = ftp.connect(param)

Connect to ftp server and log in.

Params:

param: Lua table containing ftp connection parameters
"host" FTP server domain or IP address

"port" optional; FTP server connection port; default: 21

"user" user name
"pass" user password

Returns:

res: 0 if OK, negative number on error

disconnect()

res = ftp.disconnect()

Log out and disonnect from ftp server.

Params:

nil

Returns:

res: 0 if OK, negative number on error

list(file [,option])

```
len, slist = ftp.list(file)
```

```
res = ftp.list(file, file_name])
```

```
nlin, tlist = ftp.list(file, "*totable")
```

List files on current directory of the connected ftp server.

file: file specification ("*", "*.lua", data/*.*", etc)

option: optional;

not given: the result is returned as Lua string
"file_name": the result is written to the file "file_name"
"*totable": the result is returned as Lua table

Returns:

res: 0 if save to file OK, negative number on error

tlist: Lua table containing the listing slist: Lua string containing the listing

len: string length if listing returned as string, negative number on error

nlin: number of items in table, negative number on error

recv(remote_file [,local_file])

res = ftp.recv(remote_file, local_file)

len, str_file = ftp.recv(file, "*tostring")

Receive remote file from ftp server to local file or string.

Params:

remote file: remote file name to receive

local_file: local file name

If "*tostring" the result is returned as Lua string

Returns:

res: 0 if save to file OK, negative number on error

str_file: Lua string containing the remote file

len: the length of the file received to string, negative number on error

send(file_name [,remote_file] [,"*append"])

res = ftp.send(file_name)

res = ftp.send(string, remote_file [,"*append"])

res = ftp.send(file_name, "*append")

res = ftp.send(file_name, remote_file)

res = ftp.send(file_name, remote_file, "*append")

Send local file or string to ftp server.

file name: local file name or string to send

If file with that name exists on local file system, the file is sent,

otherwise the content of this parameter is sent

and remote_file parameter is mandatory

remote_file: optional; remote file name

"*append" optional; append the file or string to remote file,

if not given overwrite remote file

Returns:

res: 0 if OK, negative number on error

chdir(remote_dir)

res = ftp.chdir(remote_dir)

Set current directory on ftp server.

Params:

remote_dir: new remote directory to set as current

Returns:

res: 0 if save to file OK, negative number on error

getdir(remote_dir)

len, res = ftp.chdir()

Get current directory on ftp server.

Params:

nil

Returns:

res: string; ftp server remote dir

len: length of res, negative number on error

mqtt module

MQTT originally stood for MQ Telemetry Transport, but is now just known as "MQTT". It is a publish/subscribe, extremely simple and lightweight messaging protocol, designed for constrained devices and low-bandwidth, high-latency or unreliable networks. The design principles are to minimize network bandwidth and device resource requirements whilst also attempting to ensure reliability and some degree of assurance of delivery. These principles also turn out to make the protocol ideal of the emerging "machine-to-machine" (M2M) or "Internet of Things" world of connected devices, and for mobile applications where bandwidth and battery power are at a premium.

This module supports MQTT communication. Multiple mqtt connections are supported. GPRS must be configured with setapn() function before using any of mqtt functions.

create(config)

mqtt_id = mqtt.create(config)

Create and configure new mqtt client connection. Returns mqtt connection id which is used in other functions.

No connection is established.

Client status can be checked with *print(mqtt id)*.

To destroy the client and free memory set mqtt id to nil.

```
Params:
```

```
config: Lua table containing mgtt client connection parameters
                        MQTT broker domain or IP address
        "host"
        "port"
                        optional; MQTT broker connection port; default: 1883
        "user"
                        optional; user name
        "pass"
                        optional; user password, mandatory if user name given
        "qos"
                        optional; QoS (Quality of Service); default 0
        "onmessage"
                        optional; Lua callback function to be executed on new message
                             function cb func(len, topic, msg)
                                 len
                                         received message length
                                         string; message topic
                                 topic
                                         string; received message
                                 msg
        "ondisconnect" optional; Lua callback function to be executed on disconnect
                             function cb func(host)
                                         the host from which the client was disconnected.
                                 host
```

Returns:sms module

mqtt_id: mqtt client id to be used in other mqtt functions or **nil** on error

connect(mqtt_id [,check_int] [,ka_int])

res = mqtt.connect(mqtt_id [,check_int] [,ka_int])

Connect to mgtt broker, set check for message and keep alive intervals.

mgtt id mgtt id obtained with create function

check int optional; interval in seconds to check for messages; default 30

5 <= check_int <= 300 & check_int <= (ka_int/2)

ka_int optional; keep alive interval in seconds; default 60

30 <= ka int <= 600

Returns:

res: 0 if connected; negative number on error

disconnect(mqtt_id)

res = mqtt.disconnect(mqtt_id)

Disconnect from mqtt broker.

Params:

mqtt_id mqtt id obtained with *create* function

Returns:

res: 0 if disconnected; negative number on error

addtopic(mqtt_id, topic [,qos])

mqtt.addtopic(mqtt_id ,topic [,qos])

Set matt client topic. Up to 5 topics can be added per client.

Params:

mqtt_id mqtt id obtained with *create* function topic string; topic name, max length 31

gos optional; topic's QoS; default: client's QoS

Returns:

nil

subscribe(mqtt_id)

mqtt.subscribe(mqtt_id)

Subscribe to topics added with addtopic() function.

Params:

mgtt id mgtt id obtained with create function

Returns:

res: 0 if subscribed; negative number on error

unsubscribe(mqtt_id [,topic])

mqtt.unsubscribe(mqtt_id [,topic])

Unsubscribe from topics added with addtopic() function or from all topics.

mgtt id mgtt id obtained with create function

topic optional; topic name to unsubscribe from; if none given, unsubscribe from all topics

Returns:

res: 0 if unsubscribed; negative number on error

publish(mqtt_id, topic, message [,qos])

mqtt.publish(mqtt_id ,topic, message [,qos])

Publish to mqtt topic.

Params:

mqtt_id mqtt id obtained with *create* function topic string; topic name, max length 31

message string; message to publish

qos optional; topic's QoS; default: client's QoS

Returns:

res: 0 if OK; negative number on error

SMS module

Functions for manipulating SMS message.

Maximum sms message length (send and receive) is 640 bytes.

send(num, msg [,cb_func])

res = sms.send(num, msg [,cb_func])

Send sms message to gsm number.

Wait for message to be sent if no cb_func is given.

Params:

num: string; gsm phone number to which to send the message

msg: string; message body

cb func: optional; Lua callback function to be executed after message is sent

function cb func(stat)

stat 0 if OK, negative number on error

Returns:

res: 0 if OK, negative number on error

numrec([box_type])

res = sms.numrec([box_type])

Check the number of received sms messages.

Params:

box_txpe: optional; message box type, default 1

0x01 <u>Inbox</u>. 0x02 <u>Outbox</u>. 0x04 Daft box.

0x08 Unsent box. Messages to be sent.

0x10 SIM card. 0x20 Archive box.

Returns:

res: number of messages, negative number on error

list([msg_state] [cb_func])

res = sms.list([msg_state] [cb_func])

Get the list of available message id's.

Params:

msg_state: optional; message state, default 1

0x01 Unread. 0x02 Read. 0x04 Sent.

0x08 Unsent (to be sent).

0x10 Draft.

cb_func: optional; Lua callback function to be executed after message list ready

function cb func(tlist)

tlist Lua table containing message id's

which can be used to read or delete the message

Returns:

res: *if cb_func is not given*:

Lua table containing message id's which can be used to read or delete the message

if cb func is not given:

Message list query result; 0: OK

read(msg_id [,cb_func])

time, msg = sms.read(msg_id)

res = sms.read(msg_id ,cb_func)

Read the message at index msg id.

Message indexes can be obtained with sms.list() function.

Params:

msg_id: message index from which to read the message

cb func: optional; Lua callback function to be executed message is read

function cb func(time, msg)

time Lua table containing message sent time

Table keys are: sec, min, hour, day, month, year

msg Lua string, the message body

Returns:

res: 0 if OK, negative number on error

time: string; message sent time msg: string; message body

delete(msg_id [,cb_func])

res = sms.delete(msg_id [,cb_func])

Delete sms message at index msg_id.

Message indexes can be obtained with sms.list() function.

Waits for message to be deleted if no cb func is given.

Params:

msg id: message index from which to delete

cb func: optional; Lua callback function to be executed after message is deleted

function cb func(stat)

stat 0 if OK, negative number on error

Returns:

res: 0 if OK, negative number on error

onmessage([cb_func])

res = sms.onmessage([cb_func])

Set Lua callback function to be executed when new message arrives. If called without parameter, removes exiting callback function reference.

cb_func: optional; Lua callback function to be executed after new message arrives

function cb_func(msg_id, gsm_num, msg)

msg id massage id

gsm_num string; phone number from which message is received

msg string; message body

Returns:

res: 0 if OK, negative number on error

sim_info()

stat, imei, imsi = sms.siminfo()

Returns SIM card status, IMEI and IMSI numbers.

Params:

nil

Returns:

stat: SIM card status:

-2 No active SIM card detected.

-1 Failed to get status.

O No SIM card is detected or the SIM card is not working.

1 The SIM card is working.

imei: IMEI number, returned only if stat=1imsi: IMSI number, returned only if stat=1

timer module

Timers are used to execute the Lua function on regular intervals. Multiple timers can be created (up to 10).

After the timer is created it can be stopped, paused, restarted, resumed and deleted.

Timer can be in one of the fallowing states:

- \diamond **running** timer is running, callback function is executed on regular intervals
- ♦ paused timer is running, but the callback function is not executed
- ♦ **stopped** timer is stopped, callback function remains registered, timer can be restarted
- ♦ **deleted** timer is stopped, callback function unreaistered, cannot be restarted

Minimal timer interval is 5 msec.

To check the timer's state and some statistics use *print(timer id)*.

Be careful when using small interval timers, it can affect performance.

create(interval, cb_func [,state])

timer_id = timer.create(interval, cb_func [,state])

Create new timer. Returns timer id which is used in other timer functions.

Timer can be created in running, stopped or paused state,

Timer status can be checked with *print(timer_id)*.

To destroy the timer and free memory set timer_id to nil.

Params:

interval: timer interval in msec

cb func: Lua callback function to be executed on timer interval

function cb func(timer id)

timer id id of the timer for which the function is called

state: optional; timer timer state after creation; default: 0

0: running

-1: running, execute callback function immediately after creation

1: paused2: stopped

Returns:

timer id: timer id to be used in other timer functions

delete(timer_id)

res = timer.delete(timer_id)

Stop and delete the timer.

To destroy the timer and free memory set timer id to **nil**.

timer id: timer id obtained with create function

Returns:

res: 0 if OK, negative number on error

pause(timer_id)

timer.pause(timer_id)

Pause the timer. Timer is running but callback function is not executed while paused.

Params:

timer_id: timer id obtained with create function

Returns: nil

resume(timer_id [,sync])

timer.resume(timer_id [,sync])

Resume paused timer. Callback function will be executed on timer interval.

Params:

timer_id: timer id obtained with create function

sync: optional; if 1, waits the next timer interval before resuming; default: 0, do not wait

Returns:

stop(timer_id)

timer.stop(timer_id)

Stop the timer. Timer is not but callback function is preserved.

Params:

timer_id: timer id obtained with create function

Returns:

start(timer_id)

timer.start(timer_id)

Start stopped timer. Callback function is executed.

Params:

timer_id: timer id obtained with create function

Returns:

nil

changecb(timer_id, cb_func)

timer.changecb(timer_id, cb_func)

Change timer's callback function.

Timer is paused first, callback function is changed, timer is resumed.

Params:

timer id: timer id obtained with create function

cb func: new Lua callback function

Returns:

changeint(timer_id, int)

timer.changeint(timer_id, int)

Change timer's interval function.

Timer is stopped first, interval is changed, timer is started.

Params:

timer_id: timer id obtained with create function

int: new timer's interval

Returns:

getid(timer_id)

id = timer.getid(timer_id)

Returns timer's internal id.

Params:

timer_id: timer id obtained with create function

Returns:

id: timer's ID

getstate(timer_id)

state = timer.getstate(timer_id)

Returns timer's current state. See create function for state v

Params:

timer id: timer id obtained with create function

Returns:

state: timer's state:

0: running1: paused2: stopped3: deleted

bt module

Bluetooth module.

Support communication via Bluetooth using SPP profile.

Lua interactive shell can be **redirected** to bluetooth SPP interface after client is connected. While redirection is active, client can send the string "<*Return2ShEll>" to redirect Lua shell to USB serial again.

start(name)

res = bt.start(name)

Turns on BT and starts bluetooth connection manager if not already started.

Makes BT visible under the name 'name'.

Host name and BT MAC address are reported id debugg logging is enabled.

Params:

name: rephone BT device name

Returns:

res: 0 if OK, negative number if error

spp_start([cb_func])

res = bt.spp_start([cb_func])

Starts bluetooth SPP profile and registers onreceive callback function if given.

BT mus be started using bt.start() function.

onconnect & ondisconnect callback functions can be registered separately.

No spp security is used, clients can connect to the device without PIN code.

Params:

cb_func optional; Lua callback function to be executed on data receive

function cb_func(addr, len, data)

addr string; client's BT MAC

len integer; data string length

data string data received from connected BT client

Returns:

res: 0 if OK, negative number if error

spp_write(data)

res = bt.spp_write(data)

Writes string to bluetooth spp connection.

If redirection to BT is active, this function does nothing.

data: string to be sent to BT connection

Returns:

res: number of written bytes if OK, negative number if error

spp_stop()

res = bt.spp_stop()

Disconnets client if connected and stops SPP profile.

Params:

none

Returns:

none

stop()

res = bt.stop()

Disconnets client if connected and stops SPP profile if active. Stops bluetooth connection manager and turns off BT.

Params:

none

Returns:

none

onconnect([cb_func])

bt.onconnect([cb_func])

Register Lua callback function which will be executed on client connect. If no cb_func is given, existing (if any) callback function is unreferenced.

Params:

cb_func: optional; Lua callback function, prototype:

function cb_func(addr, stat)

addr string; client's BT MACstat integer; connection status

Returns:

Nil

ondisconnect([cb_func])

bt.ondisconnect([cb_func])

Register Lua callback function which will be executed on client disconnect. If no cb_func is given, existing (if any) callback function is unreferenced.

Params:

optional; Lua callback function, prototype: function cb_func(addr) cb_func:

string; client's BT MAC addr

Returns:

nil

uart module

Communication over serial port.

USB serial port (/dev/ttyACM0, MTK Debug port) and **hardware UART** are supported.

Only the UART which is not used as Lua Shell input/output can be created.

create(port, cb_func [,param])

uart_id = uart.create(port, cb_func [,param])

Create new uart. Returns uart id which is used in other uart functions.

Params:

port: 0: create uart on USB serial port; 1: create uart on hw UART port cb func: Lua callback function to be executed on data received event

function cb_func(uart_id, len, data)

uart id id of the uart for which the function is called

len length of the received data

data string; received data

param: optional; Lua table containing communication parameters; default; 115200,8,1,n

Possible table key values are:

bit number of data bits: 5 ~ 8

par parity: 0 ~ 4; **0**=none; **1**=odd; **2**=even; **3**=mark; **4**=space

stop nuber of stop bits: 1 ~ 3; **1**=1; **2**=2; **3**=1.5

bdr baud rate: 75 ~ 921600;

only limits are checked, enter the correct value!

Returns:

uart id: uart id to be used in other timer functions

delete(uart_id)

uart.delete(uart_id)

Deletes the uart. Unregister callback function

Params:

uart_id: uart ID obtained with uart.create() function

Returns:

write(uart_id, data)

uart.write(uart_id, data)

Write data to uart.

Params:

uart id: uart ID obtained with uart.create() function

data: string; data to write

Returns:

term module

Term module enables advanced Lua shell terminal communication if used with ANSI/VT100 compatible terminals. Screen positioning functions are included, as well as full featured file editor and ymodem file transfer.

Clear functions

term.clrscr()

Clears the screen, position the cursor at 0,0.

term.clreol()

Clears the the current line from current x position to the end of line.

Cursor move functions

term.moveto(x,y)

Move the cursor to given position.

term.moveup(), term.moveup(), term.moveleft(), term.moveright()

Move the cursor up, down, left or right.

getlines()

lin = term.getlines()

Get current number of terminal lines.

Params: nil Returns:

lin: number of terminal lines

getcols()

col = term.getcols()

Get current number of terminal columns.

Params: nil Returns:

col: number of terminal columns

setlines(lin)

term.setlines(lin)

Set the number of terminal lines.

number of terminal lines lin:

Returns:

nil

setcols(col)

term.setcols(col)

Set the number of terminal columns.

Params:

number of terminal columns col:

Returns: nil

getcx()

x = term.getcx()

Get current character's X position.

Params: nil Returns:

> current X position x:

getcy()

y = term.getcy()

Get current character's Y position.

Params: nil Returns:

> current Y position y:

getchar([wait])

c = term.getchar([wait])

Get character from terminal input buffer or wait for one.

Some special key characters can be received, they are converted to the fallowing Lua constants which can be used for comparison:

UP, DOWN, LEFT, RIGHT, HOME, END, PAGEUP, PAGEDOWN, ENTER, TAB, BACKSPACE, ESC, DEL, INS, CTRL Z, CTRL A, CTRL C, CTRL E, CTRL T, CTRL U, CTRL K, CTRL L, UNKNOWN

When used all constants must be prefixed by module name, for example: term.HOME.

wait: if wait=1, waits for the character,

otherwise returns the scaracter from buffer if there is one

Returns:

c: ASCII code of the received character

getstr(x, y, maxlen [,outstr])

str = term.getstr(x, y, maxlen [,outstr])

Move cursor to position x,y; optionally print the given string and wait for input.

The input is terminated when Enter or Ctrl-C is pressed.

Simple line editing is possible, left&right arrow keys, Home, End, Backspace and Del keys can be used.

Params:

x: X screen position y: Y screen position

maxlen: maximum input length, 1~254

outstr: optional; string to print before input, max 128 characters

Returns:

str: received string, if Ctrl-C was pressed, an empty string is returned;

edit(file)

term.edit(file)

Edit the text file. If the file with given name does not exist, it is created.

The editing area is determined by current number of lines and columns.

Arrow keys, Home, End, Backspace, Del, PgUp, PgDown keys can be used to navigate through file. Insert key can be used to switch between insert/overwrite mode. Tab inserts 4 spaces. Ctrl-C exits editing without saving the file.

Ctrl Z exits editing and, if file was changed, prompts for saving.

When the file is read, all tab characters are converted to 4 spaces!

Params:

file: file name

Returns: none

yrecv([file_name])

term.yrecv([file_name])

Receives the file over serial line using ymodem protocol. Text and binary files can be received.

Params:

file_name: optional; save file under that name; default: save under original name

Returns:

nil prints result on terminal

ysend(file_name [,host_fname])

term.ysend(file_name [,host_fname])

Sends the file over serial line using ymodem protocol. Text and binary files can be sent.

Params:

file_name: file to send

host_fname:optional; send with different name; default: send with original name

Returns:

nil prints result on terminal

SENSOr module

Support for various sensors.

At the moment the fallowing sensors are supported:

- DHT-11/DHT-22
- Bosh Sensortec BME280 Temperature, pressure & humidity sensor in I2C mode
- DS18B20, DS18S20, DS1822 and DS28EA00
 DS1820 type sensors can be connected in "parasite power" mode in which only data &gnd pins are used. See data sheet for details.

dht_get(pin, type)

t, h, stat = sensor.dht_get(pin, type)

Read temperature and humidity from DHT-11/DHT22 sensor.

Params:

pin: GPIO pin to which the sensor data pin is connected

type: sensor type: **0**: DHT-11, **1**: DHT-22

Returns:

t: temperature h: humidity

stat: 0 if successful, negative number on error

ds_init(pin)

res = sensor.ds_init(pin)

Initiate 1-wire interface on selected pin and test if any device is connected.

Params:

pin: GPIO pin to which the DS sensor data pin is connected

Returns:

res: 1 if at least one sensor is detected; 0 if error or no device connected

ds_search()

n = sensor.ds_search()

Returns number of DS1820 devices detected on 1-wire bus.

Params: nil

Returns:

n: number of devisec detected

ds_setres(n, res)

rres = sensor.ds_setres(n, res)

Set desired measurement resolution, 9, 10, 11 or 12 bit. Higher resolution requires longer measurement time.

Params:

n: sensor device number: 1 to number of sensors detected with *sensor.ds_search*

res: resolution: 9~12 bit

Returns:

rres: actual resolution set or negative number on error

ds_getres(n)

res, mtime = sensor.ds_getres(n)

Get current resolution and expected measurement time.

Params:

n: sensor device number: 1 to number of sensors detected with *sensor.ds_search*

Returns:

res: curent sensor's resolution

mtime: expected measurement time in msec

ds_gettemp(n)

t, stat = sensor.ds_gettemp(n)

Start measurement, wait for measurement result and return it.

Params:

n: sensor device number: 1 to number of sensors detected with sensor.ds_search

Returns:

t: measured temperature in degree C, -9999 on error

stat: measurement status: 0 if measurement OK, error code on error

ds_startm(n)

res = sensor.ds_startm()

Start temperature measurement on all connected devices. Does not wait for result

Params:

n: sensor device number: 1 to number of sensors detected with sensor.ds search

Returns:

res: **0** if OK, **-1** on error (no devices connected)

ds_get(n)

t, stat = sensor.ds_gettemp(n)

Get the last temperature value. Measurement must be started with *sensor.ds_startm()*.

n: sensor device number: 1 to number of sensors detected with sensor.ds search

Returns:

t: measured temperature in degree C, -9999 on error

stat: measurement status: **0** if measurement OK, error code on error

ds_getrom(n)

rom = sensor.ds_getrom(n)

Get the ROM values (unique 8-byted sensor identification) to Lua table.

Params:

n: sensor device number: 1 to number of sensors detected with *sensor.ds_search*

Returns:

rom: Lua table containing 8 values of the sensor ID

bme280_init(addr [,mode [,per]])

res = sensor.bme280_init(addr [,mode [,per]])

Initiate BME280 sensor on I2C address. I2C interface will be initiated automatically

Params:

addr: sensor's i2c addres; 0x76 or 0x77

mode: optional; operating mode; **0**, **1** or **3**; default: 0

0: sleep mode, no operation, lowest power

1: forced mode, perform one measurement, return to sleep mode

3: normal mode, continuous measurements with inactive periods between

per: optional; standby period between measurements in normal mode in msec; default: 125

Returns:

res: 0 if OK, negative number on error

bme280 getmode()

mod, per = sensor.bme280_getmode()

Get current BME280 sensor operating mode

Params:

nil

Returns:

mode: current operating mode(0, 1, 3) if OK, negative number on error

per: current standby period in msec if OK, nil on error

bme280_setmode(mode [,per])

res = sensor.bme280_setmode(mode [,per])

Set BME280 sensor operating mode

mode: operating mode; **0**, **1** or **3**; default: 0

0: sleep mode, no operation, lowest power

1: forced mode, perform one measurement, return to sleep mode

3: normal mode, continuous measurements with inactive periods between

per: optional; standby period between measurements in normal mode in msec;

default: previous value

Returns:

res: 0 if OK, negative number on error

bme280_get()

t, h, p = sensor.bme280_get()

Get measurement results.

In normal mode, last measurement results are returned, otherwise new measurement is initiated and results returned.

Params:

nil

Returns:

t: temperature, float value in °C

h: humidity, float value in %

p: pressure, float value in Pa (Pascal)

audio module

Support for playing and recording audio.

Works with Xadow audio board, but should work with speaker and microphone connected via expansion board too.

play(file [,format])

res = audio.play(file)

Start playing audio from file.

```
Params:
```

```
file: name of the audio file

format: optional; audio format; default MP3;

the system will usually recognize the format without explicitly giving one

NONE = -1

AMR = 3

MP3 = 5,

AAC = 6

WAV = 13

MIDI = 17

IMELODY = 18

OTHER = 100
```

Returns:

res: 0 if OK, negative number on error

pause()

res = audio.pause()

Pause current playback.

Params:

nil

Returns:

res: 0 if OK, negative number on error

resume()

res = audio.resume()

Resume paused playback.

Params:

nil

Returns:

res: 0 if OK, negative number on error

stop()

res = audio.stop()

Stop current playback.

Params: nil

Returns:

res: 0 if OK, negative number on error

get_time()

t = audio.get_time()

Get current playback time.

Params: nil

Returns:

t: playback time in msec, 0 if not playing

set_volume(vol)

audio.set_volume(vol)

Set playback volume.

Params:

Vol: playback volume: 0 ~ 6

Returns:

get_volume()

vol = audio.get_volume()

Get current playback volume.

Params: nil Returns:

vol: current playback volume

record(file [,format])

res = audio.record(file)

Start recording audio to file.

If the file already exists, error code -3 will be returned.

Params:

file: name of the audio file

format: optional; audio format; default AMR;

AMR = 3 WAV = 13

Returns:

res: 0 if OK, negative number on error

rec_pause()

res = audio.rec_pause()

Pause current recording.

Params:

nil

Returns:

res: 0 if OK, negative number on error

rec_resume()

res = audio.rec_resume()

Resume paused recording.

Params:

nil

Returns:

res: 0 if OK, negative number on error

rec_stop()

res = audio.rec_stop()

Stop current recording.

Params:

nil

Returns:

res: 0 if OK, negative number on error

bit module

Bitwise operations on numbers. See the separate document *BitOp.pdf*.

json module

Lua Cjson module.

See the separate document Lua CJSON 2.1.0 Manual.pdf.

Struct module

Module for converting data to and from C structs. See the separate document *Lua struct module.pdf*.

lcd module

Module for displaying data on TFT lcd display modules with touchscreen support. See the separate document *LCD module.pdf*.
